What is needed for enhanced reductive dechlorination?

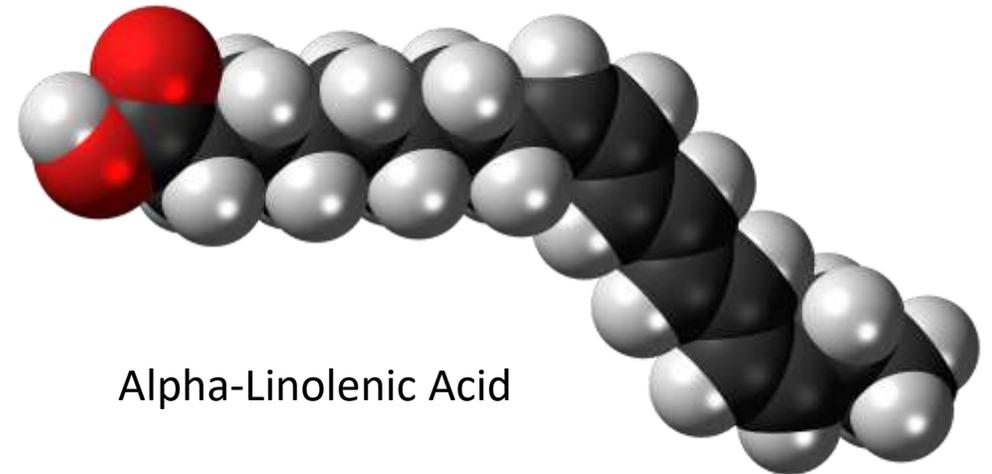

Vegetable oils ferment to acetic acid and hydrogen

Soybean Fatty Acid Distribution

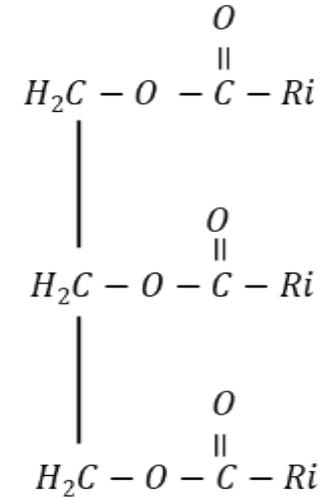

Fatty Acid		Percent
C-16:0	Palmitic	11.0 %
C-18:0	Stearic	4.0 %
C-18:1	Oleic	24.0 %
C-18:2	Linoleic	54.0 %
C-18:3	Linolenic	7.0 %

Vegetable Oil Fermentation

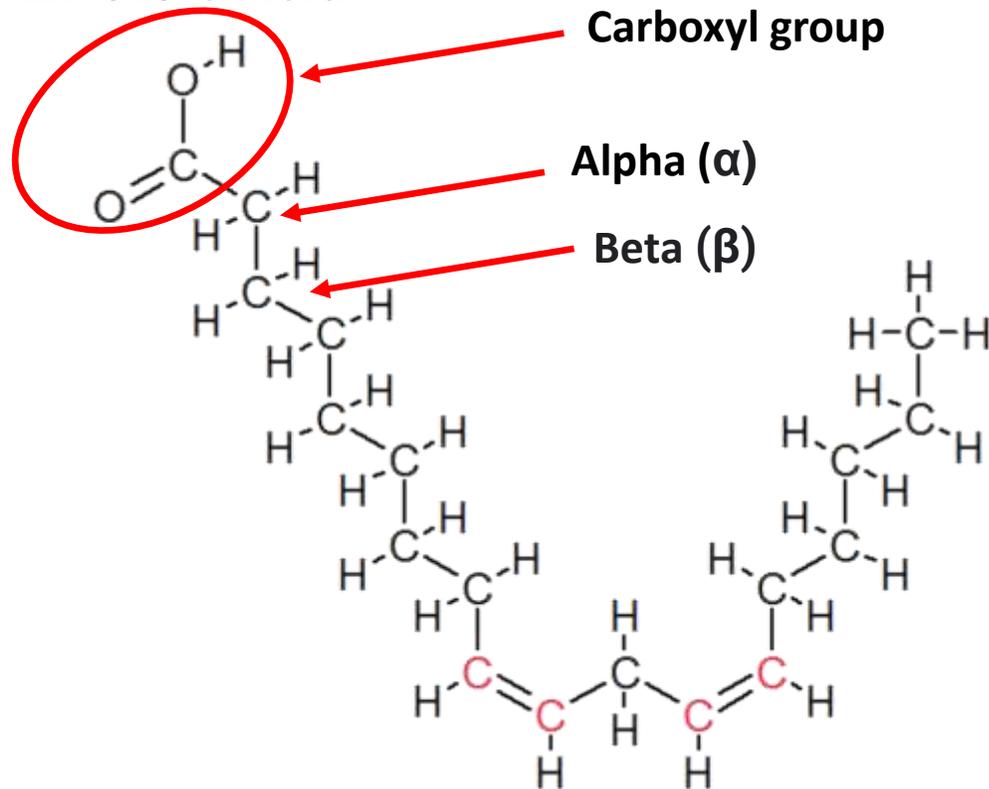

Two step process

1. Long-chain fatty acids are hydrolyzed
2. Beta-oxidation

Fatty Acid Oxidation

Linoleic Acid

Multiple step metabolic process

- Removes two carbons from the chain
- Releases:
 - Four hydrogen atoms (H)
 - Acetic Acid ($\text{C}_2\text{H}_4\text{O}_2$)

Distribution of the Correct Type of Fatty Acids is Essential

Acetate

- Slow consumption
- Will migrate downgradient
- Stimulates PCE → TCE → cDCE
- Will not stimulate cDCE → VC → ethene

Hydrogen (H₂)

Produced from linolenic acid, propionate, butyrate, etc.

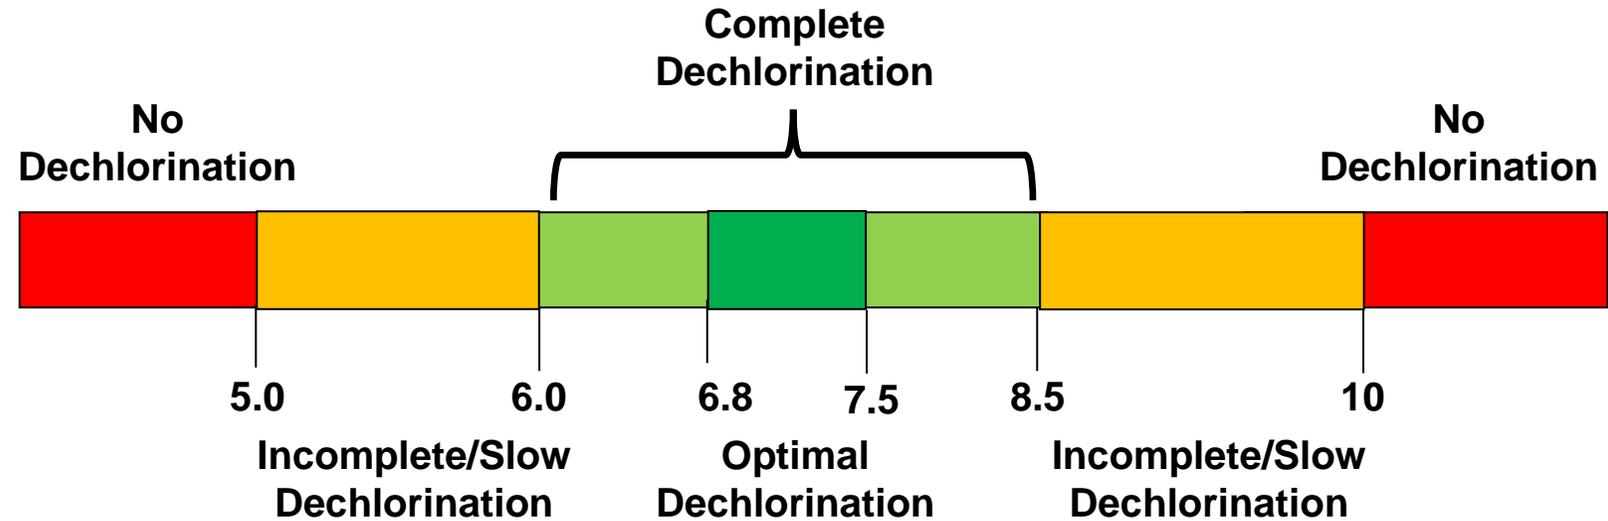

- Rapid consumption
- Does not migrate beyond injection zone
- Required for cDCE → VC → ethene

pH Plays a Key Role in VFA Production

Systems under alkaline conditions

- Enhances the activity of fatty acid-producing bacteria
- Inhibits methanogens
- Increases production of VFAs

Impact of pH on Dechlorination

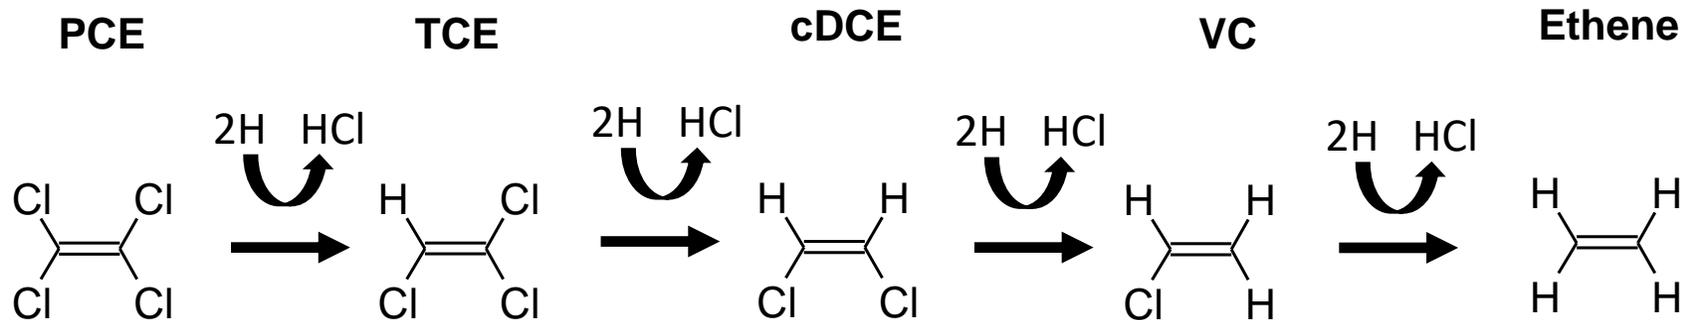

- pH of 6.0-8.5 is generally required for dechlorination to ethene*
- pH 6.8-7.5 is considered optimal range, 7.5 is best*
- Sites with low pH more likely to accumulate cDCE/VC

*Rowlands, 2004 (Slide Courtesy of SiREM)

Why is low pH so Common?

- Some sites have intrinsic groundwater pH in the 5.0-6.0 range
- Reductive dechlorination produces hydrochloric acid

- Fermentation of electron donors generates acidic byproducts

Nutrients

Impact of Fixed Nitrogen Availability on *Dehalococcoides mccartyi* Reductive Dechlorination Activity

Supporting Information

ABSTRACT: Biostimulation to promote reductive dechlorination is widely practiced, but the value of adding an exogenous nitrogen (N) source (e.g., NH_4^+) during treatment is unclear. This study investigates the effect of NH_4^+ availability on organohalide-respiring *Dehalococcoides* (Dhc) growth and reductive dechlorination in enrichment cultures derived from groundwater (PW4) and river sediment (TC) impacted with chlorinated ethenes. In PW4 cultures, the addition of NH_4^+ increased cis-1,1-dichloroethene (cDCE)-to-ethene dechlorination rates about 5-fold (20.6 ± 1.6 versus $3.8 \pm 0.5 \mu\text{M CT}^{-1} \text{d}^{-1}$), and the total number of Dhc 16S rRNA gene copies were about 43-fold higher in cocultures with NH_4^+ ($(1.8 \pm 0.3) \times 10^7 \text{ mL}^{-1}$) compared to incubations without NH_4^+ ($(4.1 \pm 0.8) \times 10^5 \text{ mL}^{-1}$). In TC cultures, NH_4^+ also stimulated cDCE-to-ethene dechlorination and Dhc growth. Quantitative polymerase chain reaction (qPCR) revealed that Coriell-type Dhc capable of N_2 fixation dominated PW4 cultures without NH_4^+ , but their relative abundance decreased in cultures with NH_4^+ amendment (i.e., 89 versus 54% of total Dhc). Pinnell-type Dhc incapable of N_2 fixation was responsible for cDCE dechlorination in TC cultures, and diazotrophic community members met their fixed N requirement in the medium without NH_4^+ . Response to NH_4^+ was apparent at the community level, and N_2 -fixing bacterial populations increased in incubations without NH_4^+ . Quantitative assessment of Dhc nitrogenase genes, transcripts, and proteomics data linked Coriell-type Dhc *nifD* and *nifK* expression with fixed N availability. NH_4^+ additions also demonstrated positive effects on Dhc *in situ* dechlorination activity in the vicinity of well PW4. These findings demonstrate that biostimulation with NH_4^+ can enhance Dhc reductive dechlorination rates; however, a “do nothing” approach that relies on indigenous diazotrophs can achieve similar dechlorination end points and avoids the potential for stalled dechlorination due to inhibitory levels of NH_4^+ or transformation products (i.e., nitrous oxide).

INTRODUCTION

Groundwater aquifers are often oligotrophic and cannot sustain high-rate reductive dechlorination desirable at sites contaminated with chlorinated solvents.^{1–7} Enhanced anaerobic bioremediation at sites impacted with chlorinated ethenes relies on biostimulation with fermentable substrates to increase hydrogen flux.^{8–11} Hydrogen is the key electron donor for organohalide-respiring *Dehalococcoides* (Dhc) strains capable of dechlorination to environmentally benign ethene.¹² *In situ* growth of Dhc in response to biostimulation with fermentable substrates has been documented,^{13–15} however, a decline in dechlorination rates and incomplete reductive dechlorination at sites that receive sufficient electron donor is a common challenge to meet remedial goals.^{16,17} While hydrogen and chlorinated ethenes meet Dhc's energy require-

ment and acetate generated by fermentation reactions serve as a carbon source, fixed nitrogen (N) availability may limit Dhc growth and reductive dechlorination activity.¹⁸

Unavailable nitrogen (N_2) must be reduced to ammonium (NH_4^+) to serve as a biological nitrogen source; however, N_2 fixation is an energetically expensive process [16 ATP consumed per N_2 molecule reduced to NH_4^+] and only occurs when NH_4^+ is limiting.¹⁹ The nitrogenase enzyme complex Nif , encoded by *nifH*, *nifD*, and *nifK* (*nif* operon), catalyzes the reduction of N_2 to NH_4^+ .²⁰ The *nifH* gene has been used as a biomarker for

- Biostimulation benefits from adding an exogenous nitrogen (N) source (e.g., NH_4^+)

- Addition of addition of NH_4^+ increased cis-1,2-dichloroethene (cDCE)-to-ethene dichlorination rates about 5-fold

- Typical target dosing:

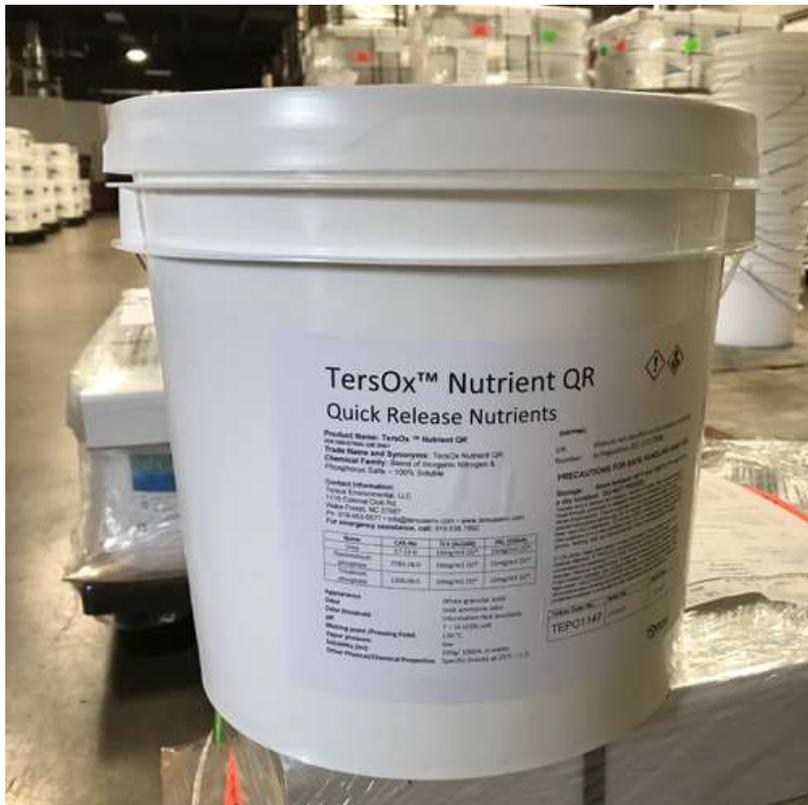

- 20:1 BOD to $\text{NH}_3 - \text{N}$ ratio
- 100:1 BOD to $\text{PO}_4 - \text{P}$ ratio

Biofouling

Nutrients in the vicinity of injection wells promote excessive biomass growth that reduce permeability

Bacterial growth within delivery wells

Hard Soap and Soap Scum

Hard Water

Calcium and Magnesium Ions

- React with the fatty acids to form an insoluble gelatinous curd

Co-solvent liquifies soap scum

Treated Samples

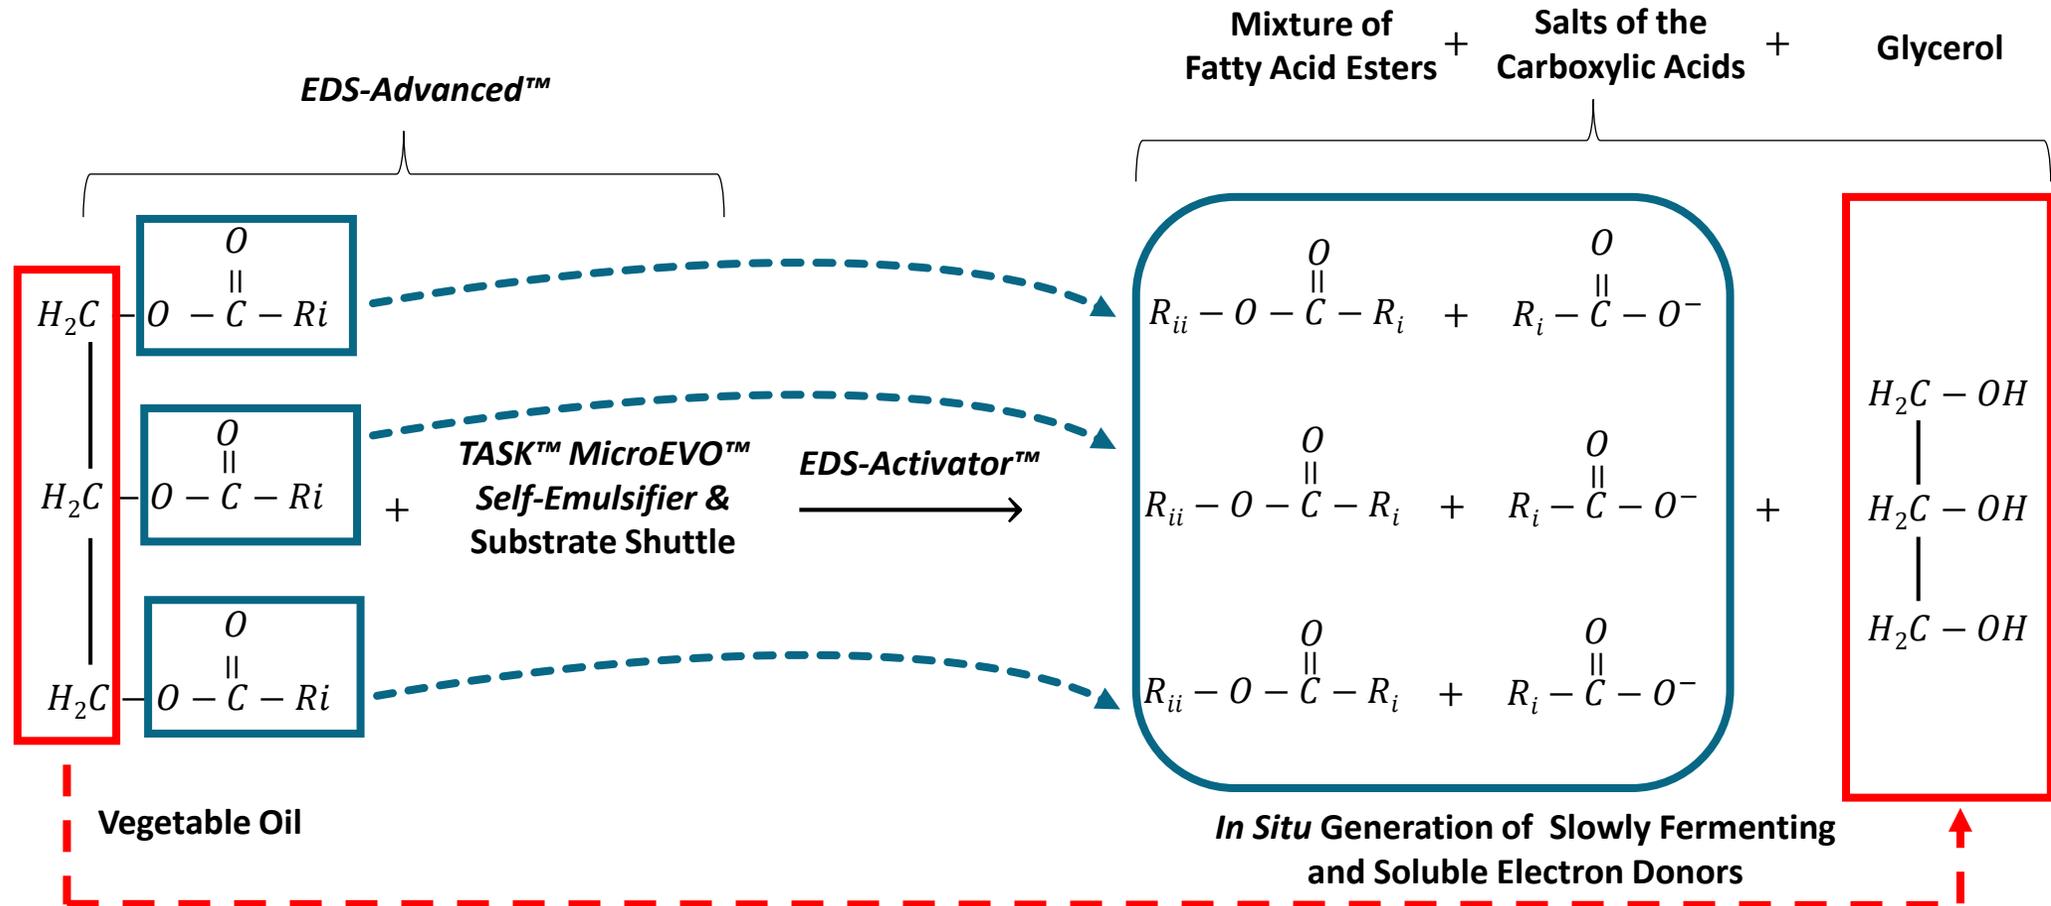

Alkaline Groundwater

Bench test to liquify viscous material

- Samples mixed with co-solvent liquifies insoluble gelatinous curd
- Addition of water, forms an EVO

Anaerobic Bioremediation Deploying Electron Donor Via *In Situ* Alcoholysis

Activator Options

- Homogeneous Alkaline Catalyst
 - Alkyl oxides (RO⁻)
- Heat
 - Steam hydrolysis
 - Electrical resistance heating
 - Thermal conduction heating
 - Gas thermal heating
 - Residual heat from an in-situ thermal remediation project
- Biocatalyst
 - Enzyme (triglyceride lipases)

EDS-Advanced™

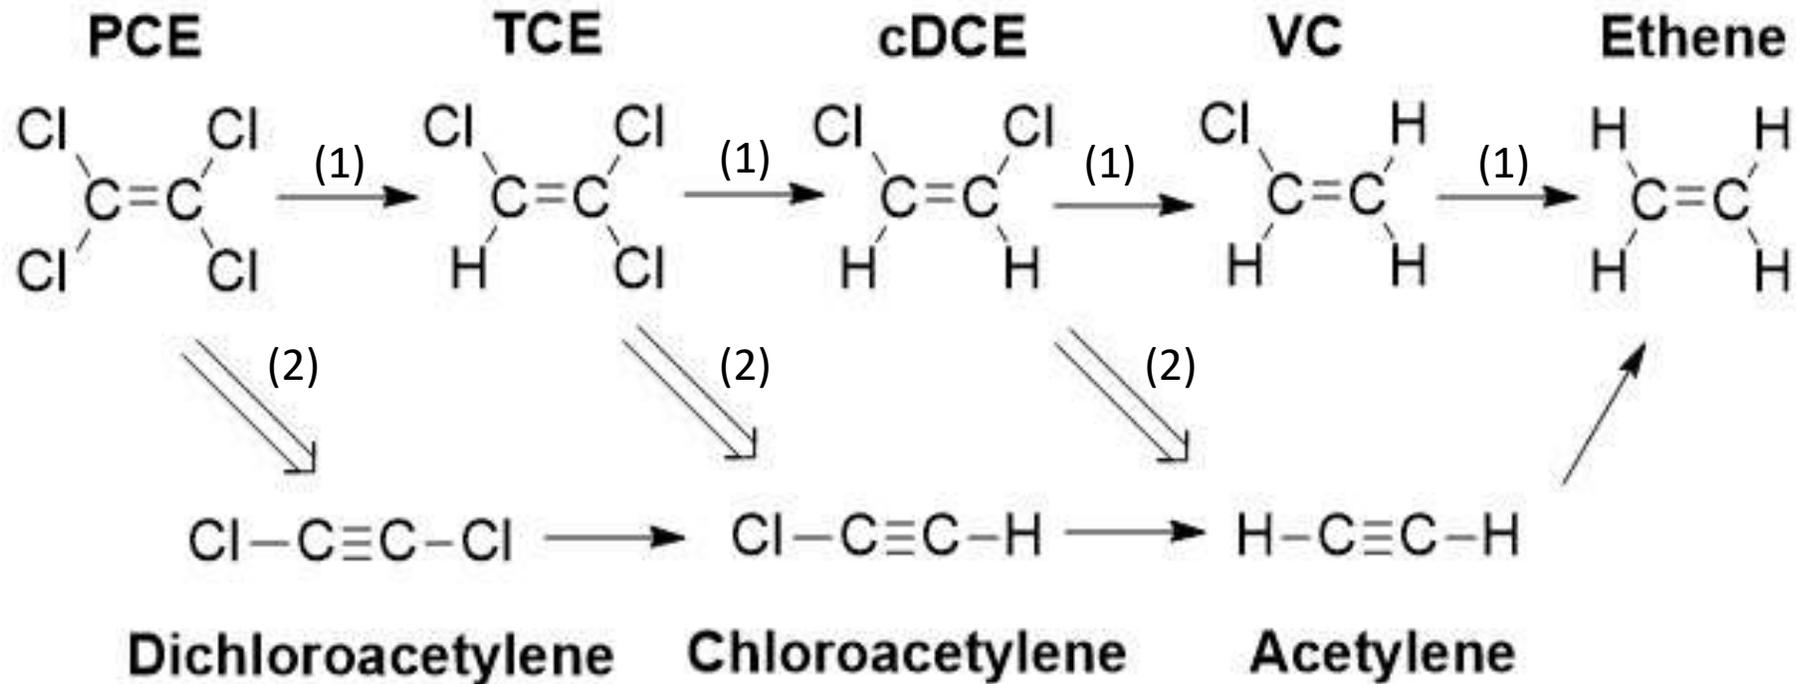

Unrestricted Electron Donor Subsurface Distribution for Anaerobic Bioremediation

- Improved subsurface distribution of a vegetable oil-based electron donor
- Improved ROI, fatty acid distribution and TOC when compared to EVO
- Eliminates dependence on EVO droplet size
- Aids in reducing cVOC inhibitory concentrations by sequestering DNAPL
- High alcohol content and high solubility reduces injection well biofouling risk

Typical Application Rates

EDS-ER™ (Soybean Oil and TASK™ MicroEVO™ Self-Emulsifier)	2 to 8 g/L
EDS-Activator™	16 to 20% of EDS-ER Dose
EDS Substrate Shuttle (Co-Solvent)	0.4 g/L
Microscale Zero-Valent Iron (mZVI)	4 to 6 g/L

ZVI Destructive Process

Pathway 1, Biotic Degradation (e.g., dichlorination of solvents)

Pathway 2, Abiotic Degradation (e.g., β elimination by ZVI or iron sulfides)

Abiotic Reduction by Iron Sulfide (FeS)

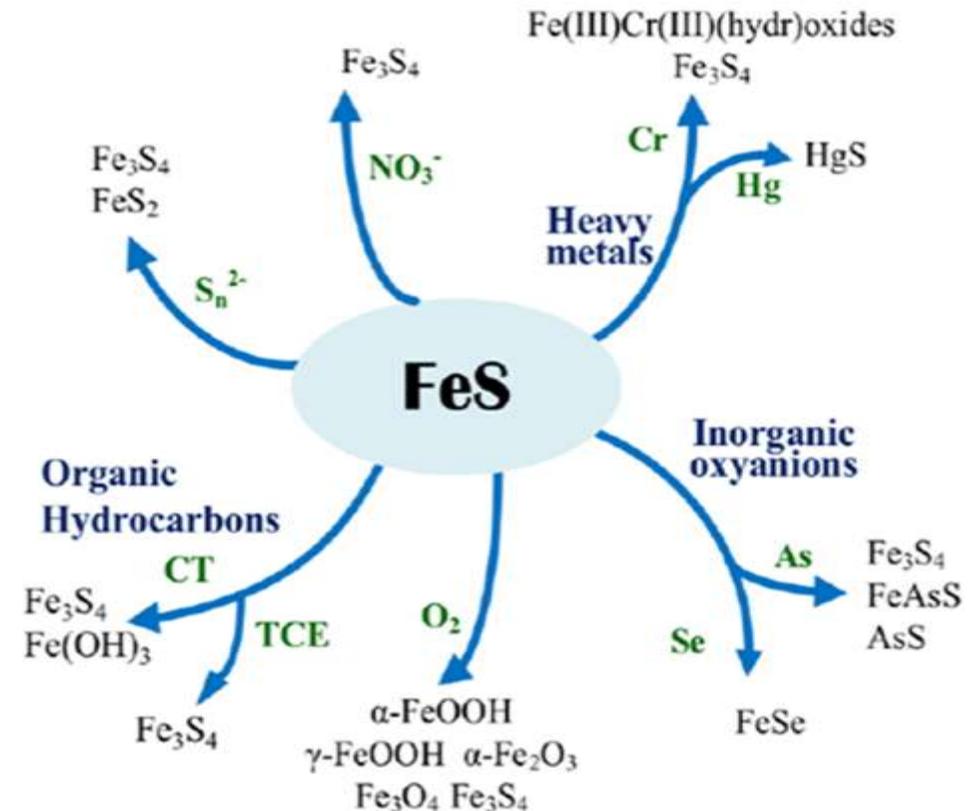

ZVI can react directly with sulfate via abiotic reaction

ZVI reacts with water to produce ferrous and H₂

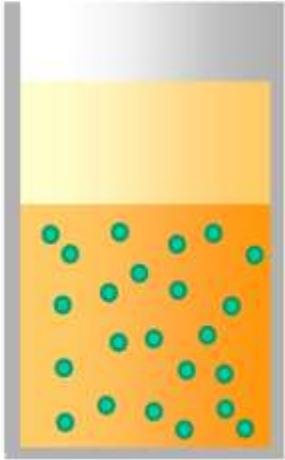

After which sulfate is reduced by H₂ to sulfide via microbially mediated reactions and forms iron sulfide precipitates

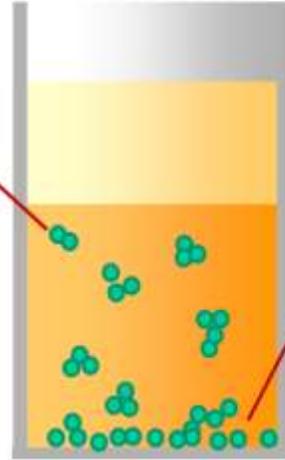

Revised from Lan, Ying, Ph.D. dissertation, University of Oklahoma, 2016.

Approaches

Example of a stable colloid

Example of an unstable colloid

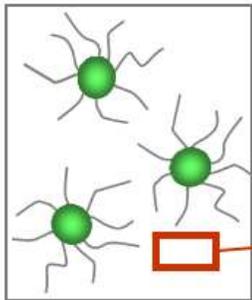

Challenges on ZVI suspension: ZVI is too heavy and simple viscosity increase does not help injectivity.

Aggregation

Sedimentation

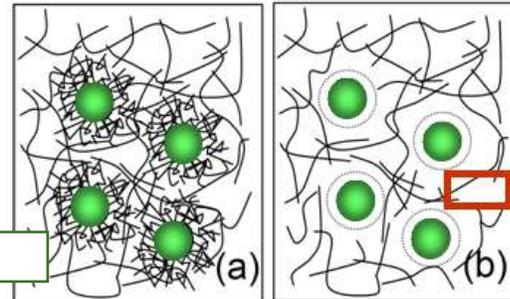

Steric stabilization

Liquid phase
(water)

(Oil)

Dispersion in a gel network

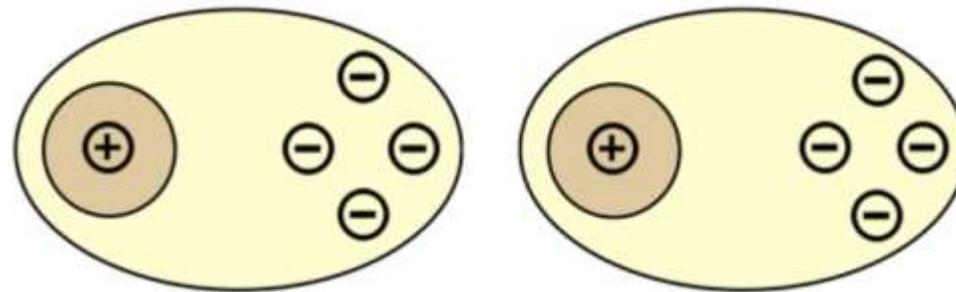

Network of polymer
chains characterized by
mechanical strength

Solution: Increase steric repulsion between ZVI particles at the least increase in viscosity. Surfactant and oil thickener were used to increase positive buoyancy.

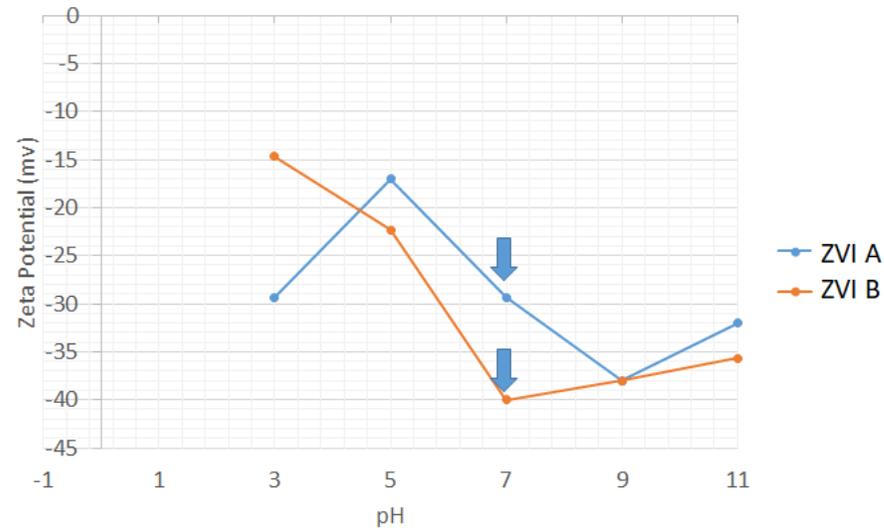

Dominant Forces in Dispersions

- Van der Waals attraction
 - Electrical double layer repulsion or attraction
 - Steric effects, mainly due to adsorbed polymers
 - Solid's particle size, density and shape
 - Liquid's viscosity and polarity
- “a suspension's stability is almost always improved by increasing the liquid's viscosity.”

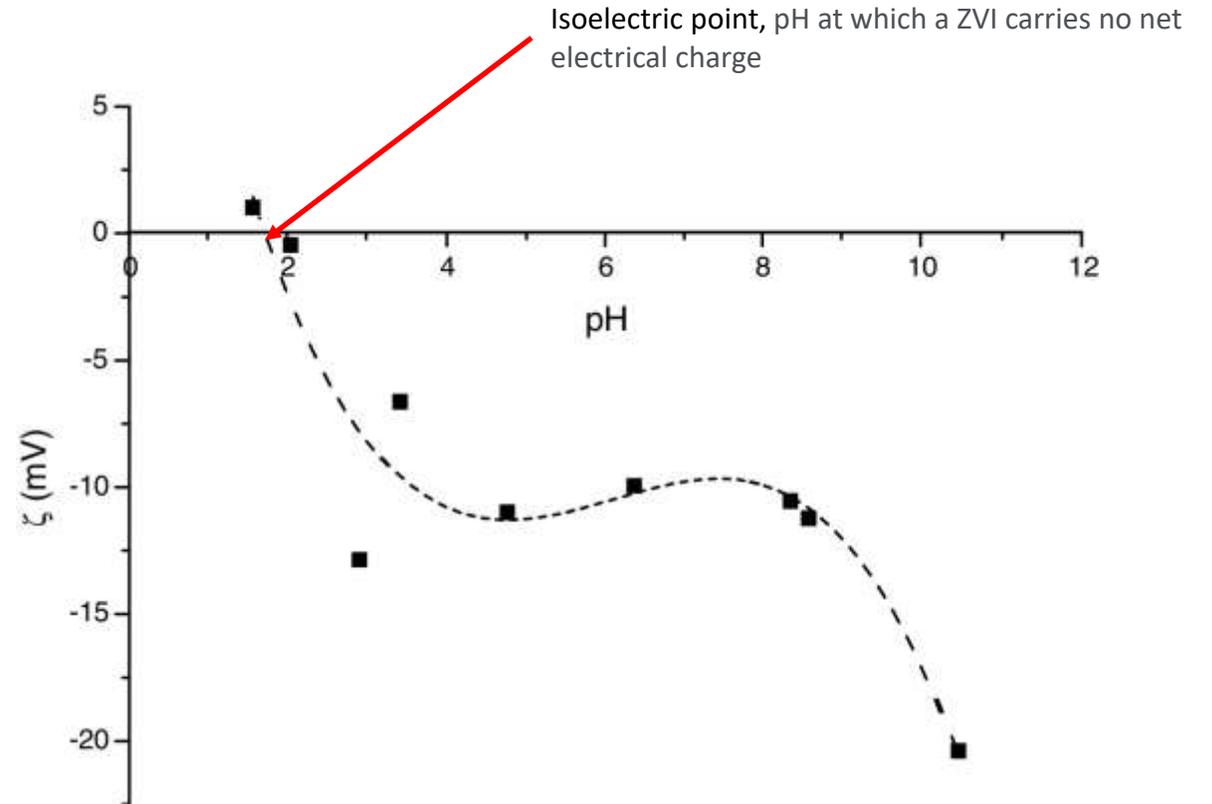

Attraction of Polarized Atoms

ZVI Zeta Potentials

- At pH 7, $\zeta = -30\text{ mV}$ & -40 mV
- At high pH, ZVI experiences deprotonation (H^+)

Viscoelastic Gels

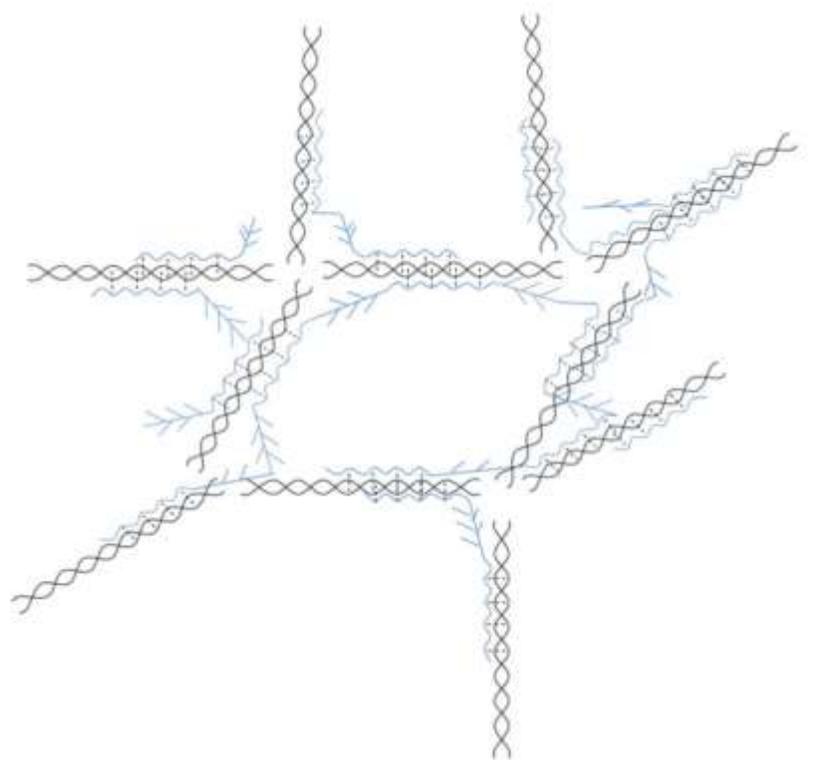

Single Biopolymer Solution (SBS)

- ZVI dispersions with diluted SBS (XG or GG) are unable to prevent sedimentation of ZVI particles (J Nanopart Res (2012) 14:1239)
 - Unfavorable alignment
 - Weak interaction among molecules
- Adsorption affect
 - ZVI particles adsorb part of polymer to their surface
 - Decrease the viscosity of suspension
 - Reduces stability

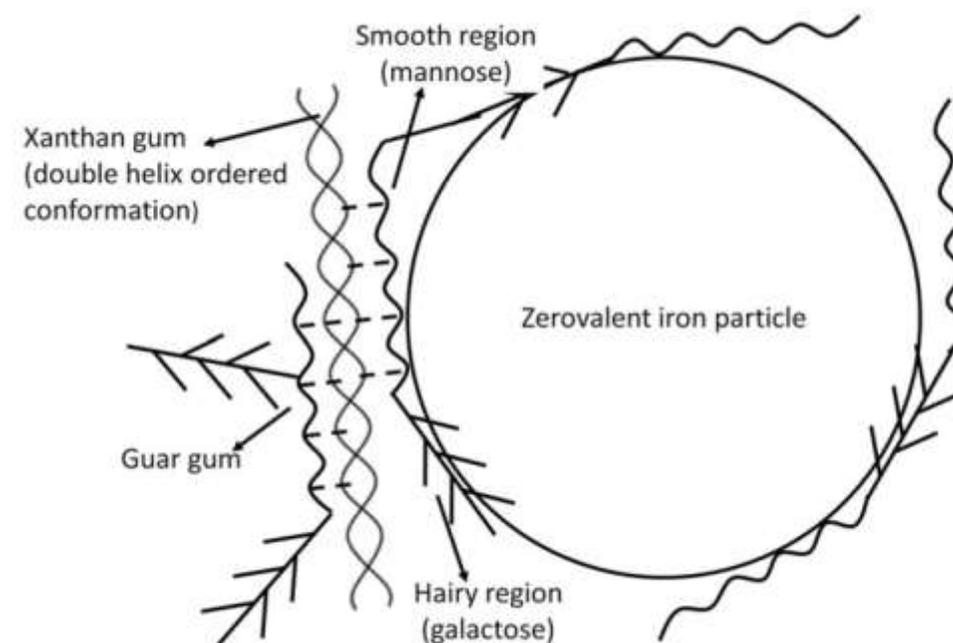

Reference: Dingqi Xue and Rajandrea Sethi. Viscoelastic gels of guar and xanthan gum mixtures provide long-term stabilization of iron micro- and nanoparticles. J Nanopart Res (2012) 14:1239

Biopolymer Mixture Solution (BMS)

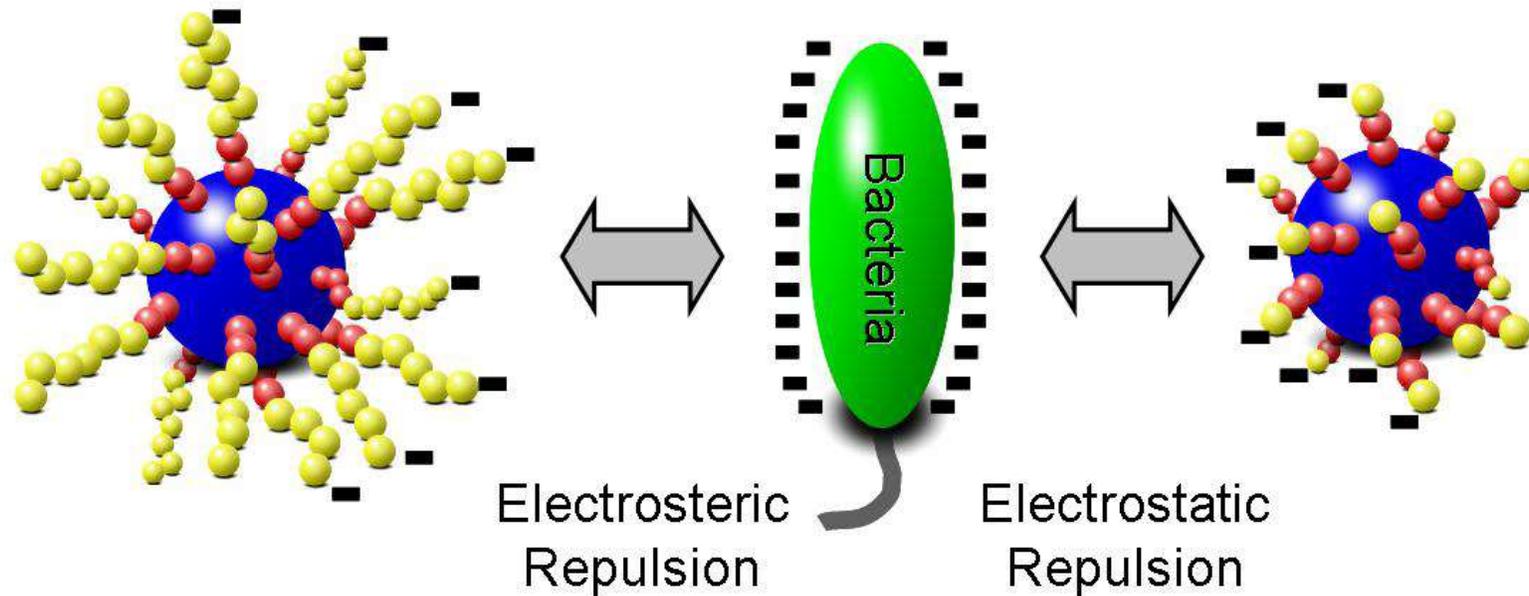

Interaction between XG and GG molecules forms a continuous network structure

GG molecules are able to adsorb to the ZVI surface (Tiraferri et al. 2008)

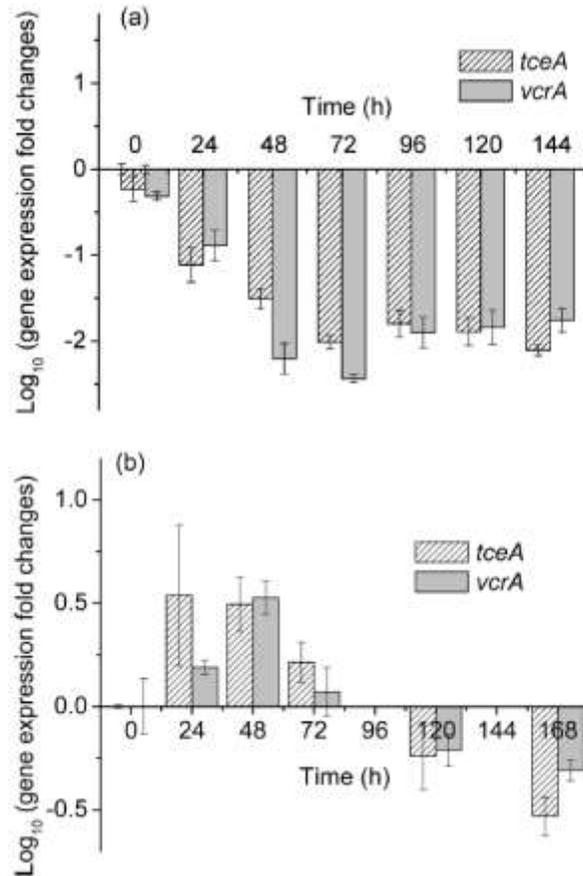

Polymer Coatings Mitigate nZVI Aggregation and Toxicity to Bacteria

Typical Design

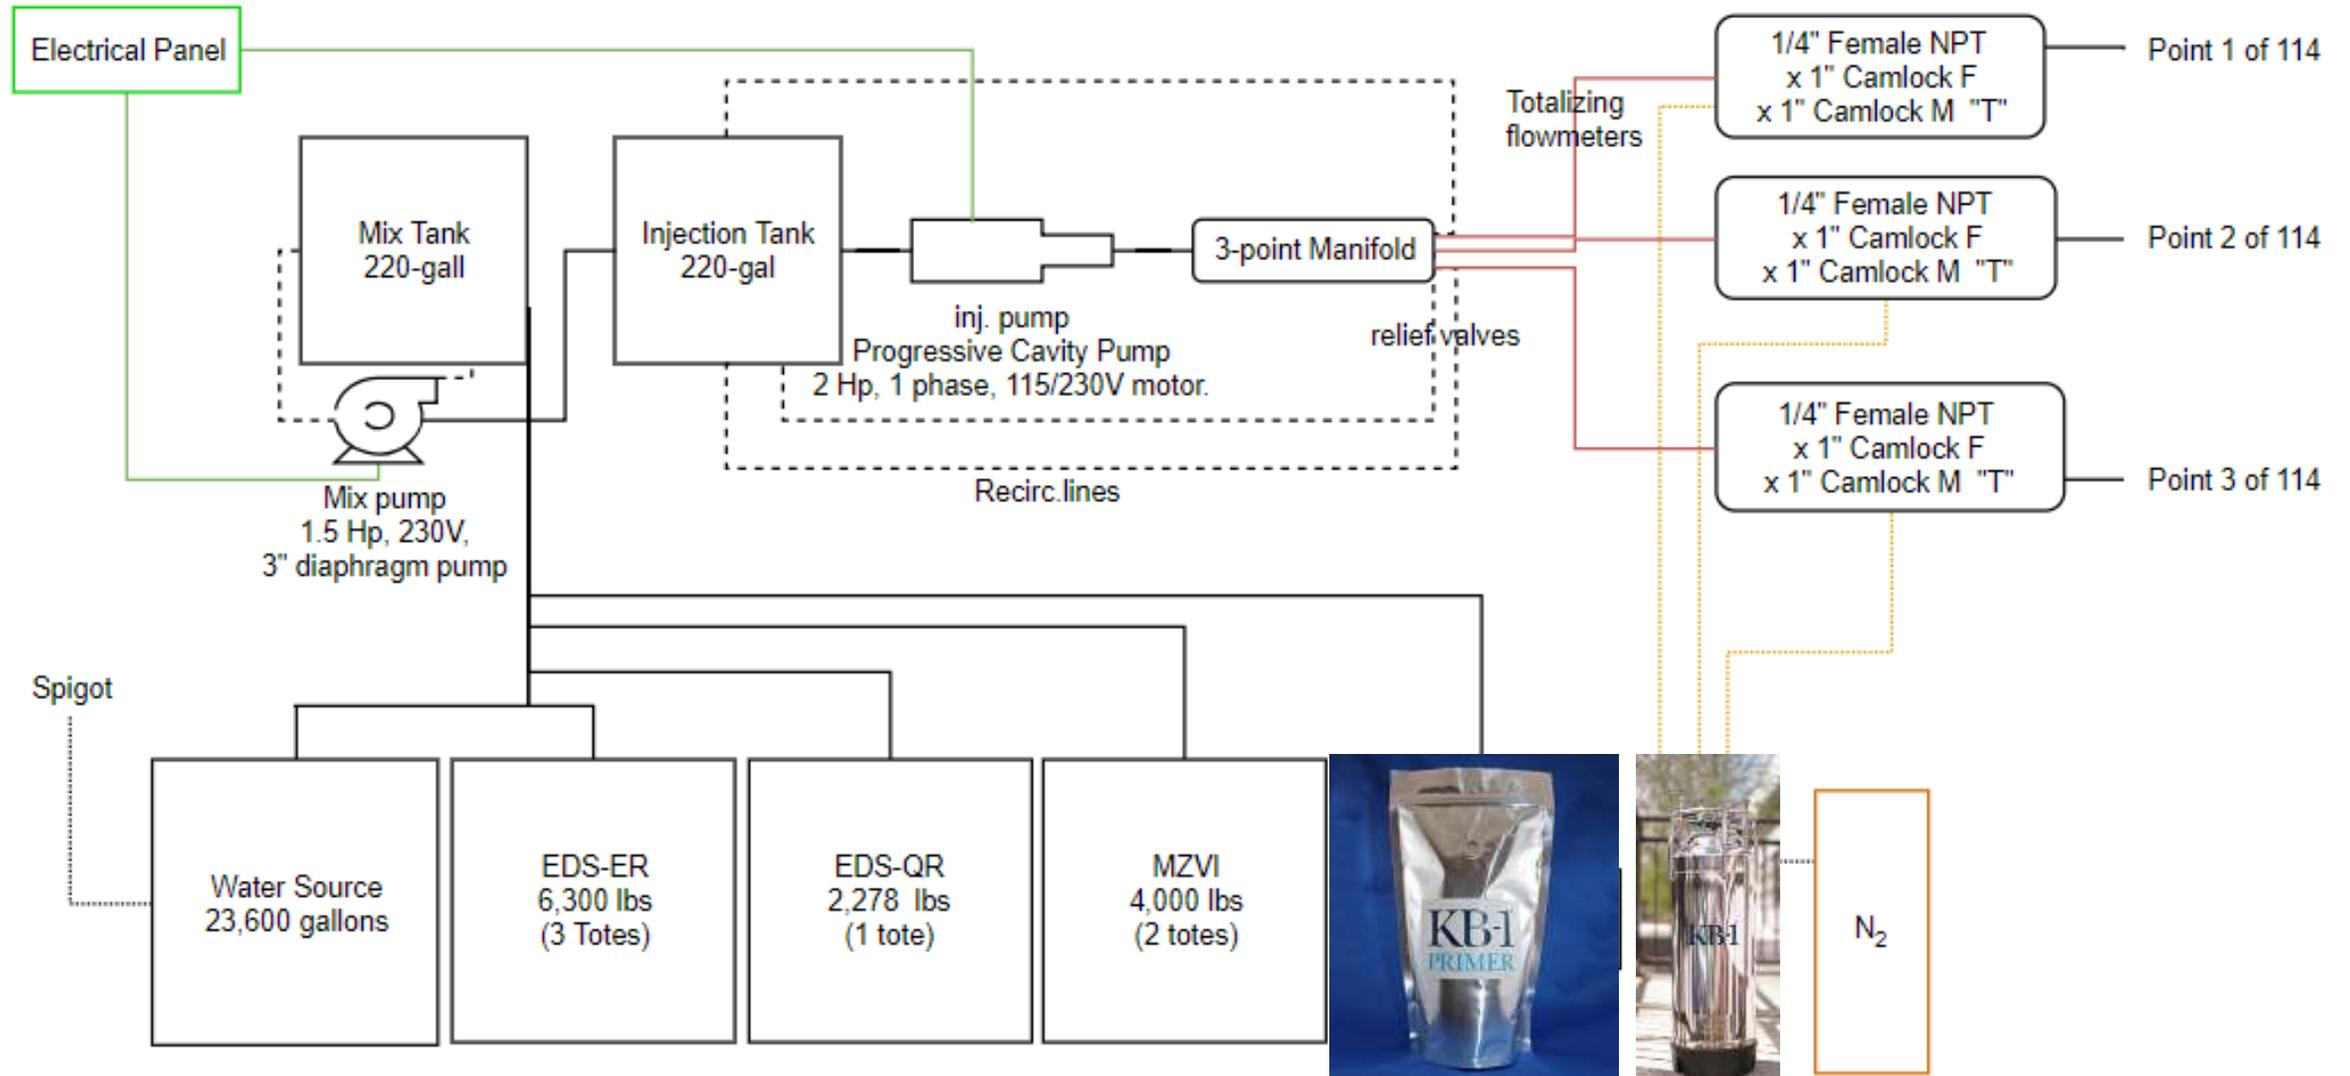

Suspension Preparation

- 3 to 7 g/L Biopolymer Mixture Solution
- 1.0 to 3.0 lbs. Crosslinker per 1,000 gallons (pH 8.5 to 10)
- 20 g/L ZVI

Post Injection Chase Water

- 1 pint to 1-gallon high pH enzyme breaker per 1,000 gallons

Field Implementation

ISCR Injection Project

- Tight, challenging location

ZVI suspension-two totes, EDS-ER™-three totes, EDS-QR™-one tote, L-Cysteine- two buckets, KB-1® culture- 55L

Manifold assembly with a small pump

Mix pump

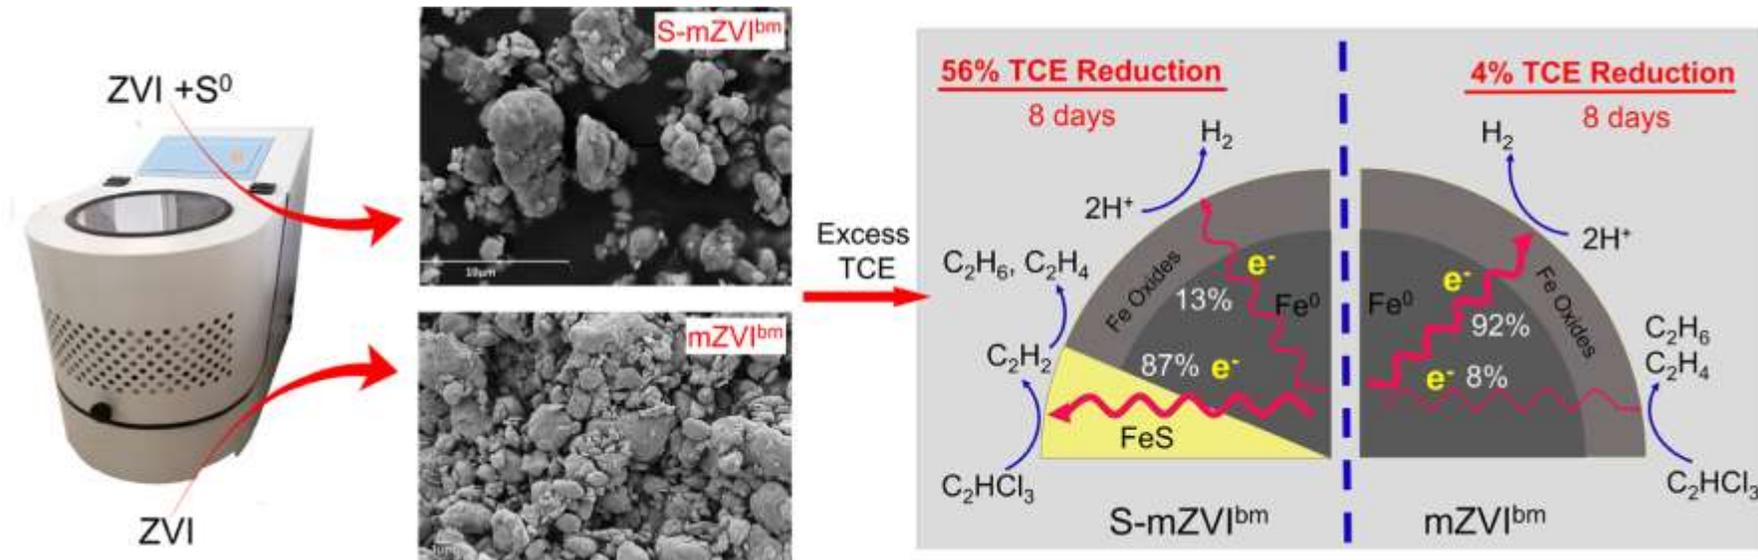

Injection Started

Dosing Considerations

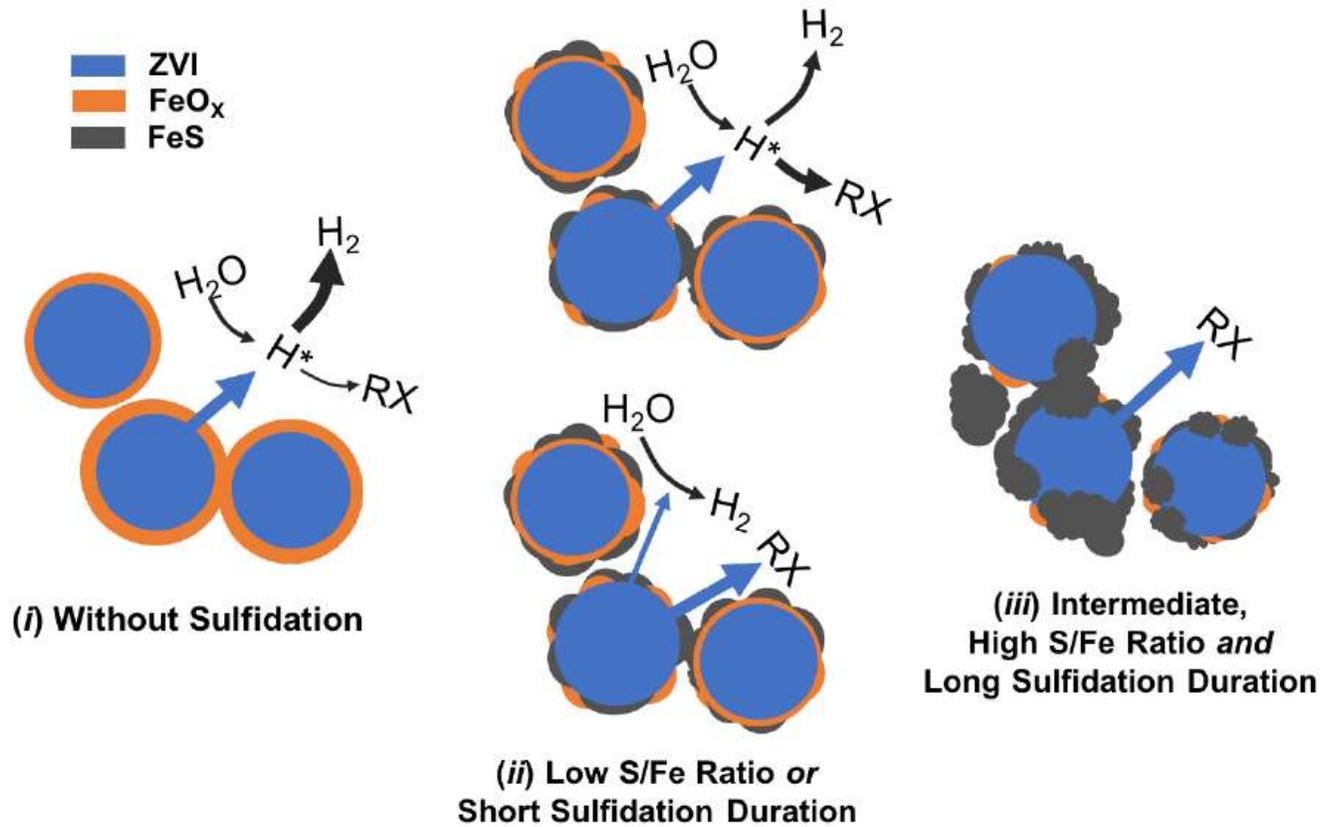

- Commodity products are typically dosed on a soil mass basis (0.5 – 1.0 wt. %). Non-uniform emplacement requires overdosing.
- mZVI Suspension is dosed based on intragranular pore volume; 4.0 to 10.0 g/L – about 10-20 percent what is used for commodity iron products.
- Less material required = lower project cost

Iron Sulfide Reagent

ISR-CI

Provides

- Benefits of sulfidated ZVI
- Higher contaminant removal efficacy
- Lower cost

Specifications

- Physical form: colloidal suspension
- Specific gravity: 1.15 - 1.22
- ORP: -700 to -1300 mV

FeS Biotic vs. Abiotic

Biotic

- Formed *in situ* by sulfate reducing microorganisms
- Must create and maintain chemical and physical ecosystem
- Requires phosphate as nutrient

Abiotic (ISR-CI)

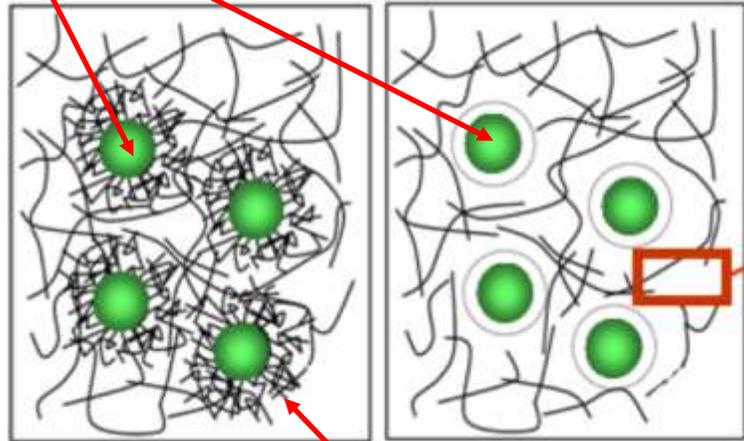

- Manufactured / formulated to a specification in a chemical reactor and delivered to site
- Transformation of FeS to Fe₃S₄ is generally faster

Packaging
